Future of European funds in a regional economy: Andalusia 2014–2020

M. Alejandro Cardenete and M. Carmen Delgado*

Department of Economics, Loyola University Andalusia, Campus Palmas Altas, 41014 Seville, Spain

Since the adhesion of Spain to the European Union, Andalusia has been catalogued as an Objective 1 region because its GDP was inferior to 75% of the community average. In this way, funds have contributed to the generation of regional GDP and reduced unemployment during these years, causing that levels exceed 75% with respect to average GDP per capita in the European Union. So, Andalusia will not be considered as one of the Objective 1 priority areas for European Regional Policy. With the changes in the region and the threat of an expected withdrawal of funds, this article proposes an analysis to explain the meaning of this withdrawal of European Funds in Andalusia in the period 2014–2020. With this aim, we develop a Dynamic Applied General Equilibrium Model that will assess the effects of the loss of this funding on the main regional economic indicators and under different simulation scenarios. The model will analyse the effect of economic policy actions on the economy, satisfying the requirements of welfare and technological feasibility when given some restrictions on available resources.

Keywords: social accounting matrix; dynamic applied general equilibrium models; regional economy; European regional policy; impact analysis

JEL Classification: E17; C68

I. Introduction

The main goals of the European Union are to boost both economic and social progress and eliminate the differences existing between the standards of living of State members and regions. Since the adhesion of Spain to the European Union, Andalusia has been catalogued as an Objective 1 region, because its GDP is inferior to 75% of the community average.

Funds have contributed to the generation of regional GDP and reduced unemployment during these years. This great performance has caused Andalusia to exit from this last group and to record levels above 75% with respect to average GDP per capita in the EU-27, according to the latest data from Eurostat.

With the changes in the region and the threat of an expected withdrawal of funds, this article proposes

*Corresponding author. E-mail: mcdelgado@uloyola.es

an analysis to explain the meaning of this withdrawal of European Funds in Andalusia in the period 2014–2020 and pursuing this goal, a Dynamic Applied General Equilibrium Model is developed to analyse the effects, expanding studies developed by Cardenete *et al.* (2013) and Lima and Cardenete (2007).

The structure of this article is as follows: the second section contains the methodology used and the main features of the model. The third presents the different simulation scenarios raised, the sharing rule for the funds established by the analysis in question and the results. Finally, the concluding remarks are found in the fourth section.

II. The Model

This section presents the dynamic CGE (computable general equilibrium) model used for the analysis. Following Cardenete and Sancho (2003), the model is formed by 25 productive sectors obtained from an aggregation of the input–output tables for Andalusia, where the domestic output of each sector (X_{dj}) uses the output of the other sectors as factors.

$$X_{dj} = \min (X_{1j}/a_{1j}, X_{2j}/a_{2j}, \dots, X_{25j}/a_{25j}, VA_j/v_j) \quad j = 1, 2, \dots, 25 \quad (1)$$

In this equation, X_{ij} represents the amount of good i required for the domestic production of good j ; a_{ij} are the equivalents to technical coefficients in the framework of input–output analysis; VA_j stands for the value added of sector j and v_j is the minimum amount of value added required to produce one unit of good j .

On the following nesting level, the regional value added of each sector j (VA_j) is the result of combining the primary factors (labour, L and capital, K) by using a Leontief fixed-coefficients technology.

$$VA_j = \min (K_j/k_j, L_j/l_j) \quad j = 1, 2, \dots, 25 \quad (2)$$

The total output (Q_j) is the result of combining the domestic output (X_{dj}) with the equivalent imports (X_{rowj}) – which are considered imperfect substitutes of domestic production – by applying the already mentioned Leontief technology. In particular, the production of sector j is given by

$$Q_j = \min (X_{dj}, X_{rowj}) \quad j = 1, 2, \dots, 25 \quad (3)$$

The government taxes the transactions between the other economic agents to obtain public revenue (R). It has an influence on the consumers' disposable income (DPI), makes transfers to the private sector (TPS) and demands goods and services (GD $_j$). The difference between revenues and payments represents the deficit or surplus of the administration.

In relation to investment and savings, the latter are considered an exogenous component, thus allowing investment to be defined endogenously. In the equilibrium situation, it is necessary to guarantee the macroeconomic equality between savings at the aggregated level and the total investment of the economy.

$$DI \text{ pinv} = DAHO \text{ pinv} + DP + DPRM \quad (4)$$

In the dynamic version following Ramsey (1928), the representative consumer maximizes the present value of the usefulness of his/her lifetime as follows:

$$\text{Max} \sum_{t=0}^7 (1/1+p)^t U(c_t) \quad (5)$$

where t is the time period, p is intertemporal discount factor, U is the utility function and c_t is consumption in period t . The consumer faces a number of restrictions. First, the total output of the economy is divided into consumption and investment, I_t . Second, capital depreciates at the rate δ . Third, the investment cannot be negative. These constraints can be written as follows:

$$c_t \leq F(K_t, I_t) - I_t \quad (6)$$

$$K_{t+1} = K_t(1 - \delta) + I_t \quad (7)$$

$$I_t \geq 0 \quad (8)$$

where K is capital and F represents the production function.

Finally, it is important to remark that the CGE model here presented follows the traditional Walrasian equilibrium doctrine, now expanded to include the public and the foreign sectors.

III. Results

The future of European Funds in Spain is now under debate. To measure the impact of the withdrawal of European Structural funds on the Andalusian economy in 2014–2020, three scenarios have been designed, based on some initial positions of the European Parliament for the next programming period. These scenarios are the following:

- (i) Conservative scenario: loss of the total amount of resources of the last period 2007–2013.
- (ii) Progressive scenario: structural funding remains at the same level as in the period 2007–2013.
- (iii) Effective/realistic scenario: loss of a third of the resources available at the 2007–2013.

Following Monrobel *et al.* (2012) and taking into account the synthesis of the interventions of Community Funds in Andalusia 2007–2013 and its endowment budget, funds will be divided up among the branches of the model taking into account the specific objectives of each of the axes and their priority issues, weighing the amounts according to the weight of each sector's productive output, a total amount of 14 585 508 thousands of euros. In addition, a corrector index is built and applied to the public sector demand variable in the CGE model. This index will be applied to the variable of public sector demand in the model. It reflects the fall in demand in the appropriate sector, which is derived from the total withdrawal of funds or the withdrawal of one-third of the funds, depending on the alternative scenarios.

Below, we present two comparisons of the conservative scenario, one of them with the continuity scenario and another with the effective/realistic scenario for GDP expenditure and its components.¹

Table 1 shows the growth rates obtained by comparing the *conservative* scenario with the *continuing* scenario and *effective/realistic* scenario. This analysis was performed on each of the components of GDP expenditure. The annual average change in GDP is observed to be around 1.2% comparing the *conservative* scenario with the *continuing* scenario and it is around 0.8% comparing

the *conservative* scenario with *effective/realistic* scenario, obtaining the variable public expenditure the highest rate of variation because it is this variable which receives the impact of the funds in the model constructed. In contrast, the investment variable is the one with the lowest rate of variation; this can be attributed to a crowding-out effect that justifies an investment downgrade by increasing public expenditure. The rate of change of the macro grows or falls from one year to the next, depending on the funds injected into the regional economy each year under study.

IV. Concluding Remarks

To complete this analysis, we conclude by emphasizing that the results obtained with the dynamic CGE model in this study on the regional economy in the 2014–2020 reveal the important contribution of European Funds to the main macroeconomic indicators, which will give rise to greater regional development in the seven years studied.

In the results presented, we have observed how the GDP would increase after receiving European Funds in Andalusia to varying degrees depending on the scenario analysed. The results show, in the case of a *continuity* scenario (which means continuing to receive the total amount of funds as in the current 7-year period, as mentioned previously), the GDP would increase an average of 1.2%, and the public expenditure variable would include a higher rate of change while investment would evidence less variation. In the case of a scenario involving more moderate funding (involving two-thirds of the amount of funds approved in the current 7-year period), the GDP would also increase, although to a lesser degree (in this case by 0.8%), thus obtaining different yearly growth rates due to growth and the funds injected into Andalusian economy during each of the years under study, as mentioned above.

All these results point to a remarkable boost in the economy in the region, thanks to Community aid. Therefore, we can conclude by saying that European funding, regardless of how it is administrated, will have a positive effect on the growth of the Andalusian regional economy in the next programming period.

¹ The results obtained in the simulations made for a number of macromagnitudes, which are magnitudes based on the scenarios previously mentioned and where an annual constant growth rate of 0.8% has been established according to economic forecasts afforded by The Economist (2012) – Economist Intelligence Unit.
